Abstract

1. Many models for the growth of trees that incorporate interspecies competition are based on a neighborhood effect assumption whereby all trees within a fixed distance of a focal tree are considered competitors. Methods and tools are needed to quantify this competitive effect and assess the quality of all resulting models.
2. We present the **forestecology** package providing methods for both 1) evaluating the effect of competitor species identity using permutation tests and 2) evaluating model performance using spatial cross-validation. Following Allen & Kim (2020), we implement a Bayesian linear regression competition model.
3. We demonstrate the package’s functionality using data from the Smithsonian Conservation Biology Institute’s large forest dynamics plot, part of the ForestGEO global network of research sites. Given ForestGEO’s data collection protocols and data formatting standards, the package was designed with cross-site compatibility in mind. We demonstrate that both 1) competitor species identity matters and 2) that not spatially cross-validating leads to error estimates that are overly optimistic.
4. The package features 1) **tidyverse**-like structure whereby verb-named functions can be modularly “piped” in sequence, 2) functions with standardized inputs/outputs of simple features **sf** package class, and 3) an S3 object-oriented implementation of the Bayesian linear regression model. These three facts allow for clear articulation of all the steps in the sequence of analysis and easy wrangling and visualization of the

geospatial forestry data. Furthermore, while the package only has Bayesian linear regression implemented, the package was designed with extensibility to other methods in mind.

Keywords: forest ecology, competition, R, Rstats, tidyverse, sf, cross-validation, spatial statistics

1 Introduction

Repeat-censused forest plots offer excellent data to test neighborhood models of tree competition Allen & Kim (2020) Canham et al. (2006) Uriarte et al. (2004). Here we describe an R package, `forestecology`, to do that. This package implements the methods in Allen & Kim (2020). It provides: a convenient way to specify and fit models of tree growth based on neighborhood competition; a spatial cross validation method to test and compare model fits Roberts et al. (2017); and an ANOVA-like method to assess whether the competitor identity matters in these models. The model is written to work with ForestGEO plot data Anderson-Teixeira et al. (2015), but we envision that it could easily be modified to work with data from other forest plots, e.g. the US Forest Service Forest Inventory and Analysis plots Smith (2002). Or more generally to model interactions of any community of mapped sessile organisms.

The `forestecology` is designed with “tidy” data principles in mind as Wickham et al. (2019).

Given that our data is of geo-spatial nature, we represent our data using the “simple features” `sf` package class of objects Pebesma (2018) whereby. While previously the `sp` package serves such purposes Pebesma & Bivand (2005), the `sf` package is designed to interface with the `tidyverse` suite of packages.

1.1 Model for growth of tree

While there are a litany of models one can consider, in Allen & Kim (2020) we considered a simple one.

We fit the following linear model to the DBH of each focal tree. Let $i = 1, \dots, n_j$ index all n_j trees of “focal” species group j ; let $j = 1, \dots, J$ index all J focal species groups; and let $k = 1, \dots, K$ index all K “competitor” species groups. We modeled the growth in diameter per year y_{ij} (in centimeters per year) of the i^{th} tree of focal species group j as a linear model f of the following covariates \vec{x}_{ij}

$$y_{ij} = f(\vec{x}_{ij}) + \epsilon_{ij} = \beta_{0,j} + \beta_{\text{dbh},j} \cdot \text{dbh}_{ij} + \sum_{k=1}^K \lambda_{jk} \cdot \text{BA}_{ijk} + \epsilon_{ij} \quad (1)$$

Link to <https://doi.org/10.1371/journal.pone.0229930.s004>

For this linear model’s case, there exists a closed form solution as described here. As such, the `fit_bayesian_model()` function using matrix algebra to obtain all parameter estimates, rather than computationally expensive Monte Carlo approximations. The inputs to this function are a `focal_vs_comp` data frame, `prior_param` a list of priors, and a boolean flag `run_shuffle` on whether or not to run competitor-species identity permutations which we will demonstrate below on the Michigan Big Woods data. This function returns the posterior means of all parameters.

2 Example

We demonstrate the `forestecology` package’s functionality on data from the Smithsonian Conservation Biology Institute (SCBI) large forest dynamics plot, located at the Smithsonian’s National Zoo and Conservation Biology Institute in Front Royal, VA, USA Bourg et al. (2013). The 25.6 ha (640 x 400 m) plot is located at the intersection of three of the major physiographic provinces of the eastern US—the Blue Ridge, Ridge and Valley, and Piedmont provinces—and is adjacent to the northern end of Shenandoah National Park. The forest type is typical mature secondary eastern mixed deciduous forest, with a canopy dominated by tulip poplar (*Liriodendron tulipifera*), oaks (*Quercus* spp.), and hickories (*Carya* spp.), and an understory composed mainly of spicebush (*Lindera benzoin*), paw-paw (*Asimina triloba*), American hornbeam (*Carpinus caroliniana*), and witch hazel (*Hamamelis virginiana*) Bourg et al. (2013).

The `forestecology` package has the following ecological goals: 1) to evaluate the effect of competitor species identity using permutation tests and 2) to evaluate model performance using spatial cross-validation. To achieve these goals, we outline a basic analysis sequence comprising of these four main steps:

1. Compute the growth of stems based on two censuses.
2. Add spatial information:
 1. Define a buffer region of trees.
 2. Add spatial cross-validation block information.

3. Identify all focal trees and their competitors.

4. Apply model, which includes:

1. Fit model.

2. Compute fitted/predicted values.

3. Visualize posterior distributions.

We start by loading all necessary packages.

```
library(tidyverse)
library(lubridate)
library(sf)
library(patchwork)
library(forestecology)
library(blockCV)
```

2.1 Step 1: Compute the growth of trees based on census data

The first step in our analysis sequence is to compute the growth of trees using data from two censuses. The `compute_growth()` function computes average annual growth assuming census data that roughly follows ForestGEO standards. Despite such standards, minor variations will still exist between sites, thereby necessitating some data wrangling and checking. For example, the SCBI site records all diameters at breast height (DBH) in millimeters Bourg et al. (2013), whereas the Michigan Big Woods site records them in centimeters Allen et al. (2020).

We load both 2008 and 2014 SCBI census data `.csv` files as they existed on GitHub on November 20, 2020. After selecting only the relevant variables, we perform a few additional data wrangling steps: convert the character variable with the date of measurement to be of explicit type `date`, convert DBH to be in centimeters¹, convert the `sp` variable containing

¹A rule of thumb to determine the units of DBH is to check if the smallest non-zero and non-missing measurement is 1 or 10. If the former, then centimeters. If the latter, then millimeters. This is because ForestGEO protocols state that only trees with DBH greater or equal to 1cm should be included in censuses.

73 species information from type `chr` character to `fct` factor.² Furthermore, in order to speed
74 up computation for purposes of this example, we only consider a 9 ha subsection of the
75 25.6 ha of the SCBI site: `gx` from 0–300 instead of 0–400 and `gy` from 300–600 instead of
76 0–640.

```
census_2013_scbi <- read_csv("scbi.stem2.csv") %>%
  select(stemID, sp, date = ExactDate, gx, gy, dbh, codes, status) %>%
  mutate(
    date = mdy(date),
    dbh = as.numeric(dbh)/10,
    sp = factor(sp)
  ) %>%
  filter(gx < 300, between(gy, 300, 600))

census_2018_scbi <- read_csv("scbi.stem3.csv") %>%
  select(stemID, sp, date = ExactDate, gx, gy, dbh, codes, status) %>%
  mutate(
    date = mdy(date),
    dbh = as.numeric(dbh)/10,
    sp = factor(sp)
  ) %>%
  filter(gx < 300, between(gy, 300, 600))
```

77 These two data frames are then supplied as arguments to the `compute_growth()` func-
78 tion, along with the `id` argument that specifies the variable that uniquely identifies each
79 tree-stem. Note furthermore that we discard all resprouts in the later census (those with
80 `code == R`), since we are only interested in the diameter growth of surviving, and not
81 resprouted, stems.

²In our spatial cross-validation algorithm in Section 2.6 issues can occur when rare species do not occur in the training set, but then are encountered in the test set. This risk is mitigated by representing `sp` as a factor variable, which has a complete list of all levels of the categorical variable.

```

growth_scbi <-
  compute_growth(
    census_1 = census_2013_scbi,
    census_2 = census_2018_scbi %>% filter(!str_detect(codes, "R")),
    id = "stemID"
  )
growth_scbi
## Simple feature collection with 7954 features and 8 fields
## geometry type: POINT
## dimension: XY
## bbox: xmin: 0.2 ymin: 300 xmax: 300 ymax: 600
## CRS: NA
## # A tibble: 7,954 x 9
##   stemID sp      dbh1 codes1 status dbh2 codes2 growth
##   <dbl> <fct> <dbl> <chr> <chr> <dbl> <chr> <dbl>
## 1      4 nysy  13.6 M      A      14.2 M      0.103
## 2      5 havi   8.8 M      A      9.6 M;P     0.150
## 3      6 havi   3.25 NULL A      4 M      0.140
## 4     77 qual  65.2 M      A     66 M      0.141
## 5     79 tiam  47.7 M      A     46.8 M     -0.161
## # ... with 7,949 more rows, and 1 more variable: geometry <POINT>

```

The output `growth_scbi` is a single data frame of class `sf` that includes variables `growth`, the average annual growth in DBH (cm y⁻¹) for all stems that were alive at both time points, and `geometry`, the `sf` package's encoding of geolocations of type `<POINT>`. Furthermore, the variables that should remain unchanged between censuses appear only once, such as location variables `gx` and `gy`; as well as species-related variables. Variables that should change between censuses are suffixed with 1 and 2 indicating the earlier and later censuses, such as `dbh1/dbh2` and `codes1/codes2`. The data format of other sites may be such that our `compute_growth()` function doesn't work at all. However, in the end, all that matters is that the growth of all stems is saved in a data frame of class `sf` and, at a

Figure 1: Compute growth of trees based on census data: Map with growth of all trees from a 9 ha subsection of the Smithsonian Conservation Biology Institute (SCBI) forest plot.

minimum, the data contains the variables above. TODO: enumerate what these variables are and say if they need exact names

Given that `growth_scbi` is of class `sf`, it can be easily plotted in `ggplot2` using the `geom_sf()` geometry as seen in Figure 1.

```
# TODO: Rescale points in this plot
ggplot() +
  geom_sf(data = growth_scbi, aes(size = growth)) +
  scale_size(breaks = c(0.01, 0.1, 1), range = c(0.1, 1))
```

2.2 Step 2: Add spatial information

The next step in our analysis sequence is to add additional spatial information to our main `growth_scbi` data frame. The first element of spatial information we add is a “buffer region” to the periphery of the study region. Since some of our model’s explanatory variables are

cumulative (such as competitor basal area), we must ensure that all trees being modeled are not biased to have different neighbor structures. This is of concern for trees at the boundary of study regions, for which all neighbors will not be included in the censused stems. In order to account for such edge effects, only trees that are not part of this buffer region, i.e. are part of the interior of the study region, will have their growth modeled (Waller & Gotway (2004)).

Our model of interspecific competition relies on a spatial definition of who the competitor trees are for focal trees of interest: all trees within a distance `comp_dist` of a focal tree are considered its competitors (assuming the same units as the `gx` and `gy` location variables). In our case we set this value at 7.5m, a value informed by Canham et al. (2004) Uriarte et al. (2004) Canham et al. (2006). Using this value along with a manually constructed `sf` object representation of the study region's boundary, we apply the `add_buffer_variable()` to our `growth_scbi` data frame to add a `buffer` boolean variable: all trees who have `buffer` set to `FALSE` will be our focal trees whose growth will be modeled, whereas those with `TRUE` will only be considered as competitor trees whose growth will not.

```
# Define buffer region using competitive distance range
comp_dist <- 7.5

study_region_scbi <- tibble(
  x = c(0, 300, 300, 0, 0),
  y = c(300, 300, 600, 600, 300)
) %>%
  sf_polygon()

growth_scbi <- growth_scbi %>%
  add_buffer_variable(size = comp_dist, region = study_region_scbi)
```

The second element of spatial information are blocks corresponding to folds of a spatial cross-validation algorithm used to estimate out-of-sample model error. Conventional cross-validation algorithms assign observations to folds by randomly resampling individual observations. However, many of these algorithms assume that the observations are

118 independent of each other. In the case of forest census data, observations exhibit spatial
119 autocorrelation. We therefore incorporate this spatial dependence into the cross-validation
120 algorithm with our spatial blocks of trees. Roberts et al. (2017) Pohjankukka et al. (2017).

121 In the example below, we first manually define four folds that partition the study
122 region as an `sf` object. We then use the output of the `spatialBlock()` function from the
123 `blockCV` package to associate each tree in `growth_scbi` to the correct fold (saved in the
124 `foldID` variable) Valavi et al. (2019).³

```
# Manually define spatial blocks to act as folds
n_fold <- 4
fold1 <- rbind(c(0, 300), c(150, 300), c(150, 450), c(0, 450))
fold2 <- rbind(c(150, 300), c(300, 300), c(300, 450), c(150, 450))
fold3 <- rbind(c(0, 450), c(150, 450), c(150, 600), c(0, 600))
fold4 <- rbind(c(150, 450), c(300, 450), c(300, 600), c(150, 600))

blocks_scbi <- bind_rows(
  sf_polygon(fold1), sf_polygon(fold2), sf_polygon(fold3), sf_polygon(fold4)
) %>%
  mutate(folds = c(1:n_fold) %>% factor())

# Associate each observation to a fold
spatial_block_scbi <- spatialBlock(
  speciesData = growth_scbi, k = n_fold, selection = "systematic",
  blocks = blocks_scbi, showBlocks = FALSE, verbose = FALSE
)

growth_scbi <- growth_scbi %>%
  mutate(foldID = spatial_block_scbi$foldID %>% factor())
```

125 Figure 2 illustrates the net effect of adding these two elements of information to the

³In the Appendix we present an example where the folds themselves are also created using the `spatialBlock()` function given a specified `cv.block.size`.

Figure 2: Add spatial information: Buffer region and spatial cross-validation blocks (1 through 4). All trees in the interior of the study region (i.e. not part of buffer) will be the focal trees whose growth will be modeled.

126 `growth_scbi` data frame. The location of each tree is marked with an integer indicating
 127 which fold it belongs to, where the folds are marked with solid lines. The color of each digit
 128 indicates whether the tree is part of the buffer region (and thus will only be considered as
 129 a competitor tree in our model) or is part of the interior of the study region (and thus is a
 130 focal tree whose growth is of modeled interest).

```
ggplot() +
  geom_sf(data = blocks_scbi, fill = "transparent", linetype = "dashed") +
  geom_sf_text(data = growth_scbi %>% sample_n(1000), aes(label = foldID, col = buffer))
```

131 2.3 Step 3: Identify all focal and corresponding competitor trees

132 The next step in our analysis sequence is to identify all focal trees and their corresponding
 133 competitor trees. The `create_focal_vs_comp()` functions performs these tasks and returns
 134 a new data frame of type `sf`. On top of the previous arguments `comp_dist` defining the

135 competition neighborhood and `id` indicating which variable uniquely identifies each tree-
 136 stem, this function also requires an `sf` object representation of the spatial cross-validation
 137 blocks/folds; in our case, this was manually encoded in the `blocks_scbi` in Section 2.2 while
 138 in our Appendix we present an example where this was performed using `spatialBlock()`
 139 from the `blockCV` package. We present the resulting data frame below with the `foldID`
 140 variable omitted for compactness of presentation.

```
# TODO: Below reconcile the number of rows as they off by one from growth_scbi %>%
# filter(!is.na(growth) & !buffer). Perhaps by removing NA's in the growth_scbi stage?
focal_vs_comp_scbi <- growth_scbi %>%
  create_focal_vs_comp(comp_dist, cv_grid_sf = blocks_scbi, id = "stemID")
focal_vs_comp_scbi %>%
  select(-foldID)

## # A tibble: 6,296 x 6
##   focal_ID focal_sp   dbh   geometry growth comp
##   <dbl> <fct>     <dbl>   <POINT>   <dbl> <list>
## 1         4 nysy    13.6 (14.2 428)  0.103 <tibble [20 x 4]>
## 2         5 havi     8.8  (9.4 436)  0.150 <tibble [32 x 4]>
## 3        79 tiam    47.7  (40 381) -0.161 <tibble [20 x 4]>
## 4        80 caca     5.15 (38.7 422)  0.253 <tibble [12 x 4]>
## 5        96 libe     2.3  (60 310)  0.262 <tibble [14 x 4]>
## # ... with 6,291 more rows
```

141 The resulting data frame `focal_vs_comp_scbi` has 6296 rows, representing the subset
 142 of the 7954 trees in `growth_scbi` that will be considered as focal trees. Two new variables
 143 `focal_ID` and `focal_sp` relate to tree-stem identification and species information. Most
 144 notably however is a new variable `comp` which contains information on all competitor trees
 145 for a given focal tree, saved in `tidyr` package list-column format Wickham (2020). For
 146 example, we drill-down on the tree with `focal_ID` 4, which has 20 competitor trees each
 147 described by 4 variables as indicated by the fact that `comp` is a `<tibble [20 × 4]>`.

Figure 3: Identify all focal and corresponding competitor trees: All 20 competitor trees of focal tree 4.

```
focal_vs_comp_scbi %>%
  filter(focal_ID == 4) %>%
  select(focal_ID, dbh, comp)
## # A tibble: 1 x 3
##   focal_ID  dbh comp
##   <dbl> <dbl> <list>
## 1       4  13.6 <tibble [20 x 4]>
```

The spatial distribution of these trees is visualized in Figure 3: the dashed circle extends 7.5 m away from the focal tree while all 20 competitor trees are within this circle.

Using the `unnest()` function from the `tidyr` package, we can flatten list-column into regular columns. We observe that for the same focal tree, we have information on all 20 competitor trees whose `dist` distance to the focal tree is ≤ 7.5 : their unique tree-stem ID number, their species, and their basal area (in m^2) calculated as $\frac{\pi \times (\text{DBH}/2)^2}{10000}$ where DBH is the value from the earlier of the two censuses in cm. Saving our focal versus competitor information in list-column minimizes redundancy since we do not repeat information on the focal tree 20 times.

```
focal_vs_comp_scbi %>%
  filter(focal_ID == 4) %>%
  select(focal_ID, dbh, comp) %>%
  unnest(cols = "comp")
```

```
157 ## # A tibble: 20 x 6
158 ##   focal_ID   dbh comp_ID   dist comp_sp comp_basal_area
159 ##   <dbl> <dbl>   <dbl> <dbl> <fct>         <dbl>
160 ## 1       4  13.6   1836  7.48 tiam          0.0176
161 ## 2       4  13.6   1847  2.81 nysy          0.00332
162 ## 3       4  13.6   1848  1.62 nysy          0.00396
163 ## 4       4  13.6   1849  2.62 nysy          0.00535
164 ## 5       4  13.6   1850  2.98 havi          0.00472
165 ## # ... with 15 more rows
```

2.4 Step 4: Fit model

Now that we've identified all focal and corresponding competitor trees and saved this information in a data frame of type `focal_vs_comp`, the final step in our analysis sequence is to fit a model for the growth of all focal trees. Currently the `forestecology` package can only fit the competition Bayesian linear regression model outlined in Section 1.1 using the `comp_bayes_lm()` function. However, any model implemented in a function that similarly takes an input data frame of type `focal_vs_comp` as an argument can be easily swapped in. For our specific competition Bayesian linear regression model, we also specify prior distributions on all parameters of interest (here chosen to be the defaults as specified in `?comp_bayes_lm`).

```
# TODO: Add information about default priors in ?comp_bayes_lm()
comp_bayes_lm_scbi <- focal_vs_comp_scbi %>%
  comp_bayes_lm(prior_param = NULL)
```

The returned `comp_bayes_lm_scbi` output is an object of S3 class type `comp_bayes_lm`

177 which contains the posterior values of all parameters in our competition Bayesian lin-
 178 ear regression. This class of object includes generic methods implemented for `print()`,
 179 `predict()`, and `ggplot2::autoplot()`. First the generic for `print()` displays the names
 180 of all prior & posterior parameters along with the model formula:

```
comp_bayes_lm_scbi
## Bayesian linear regression model parameters with a multivariate Normal likelihood.
##
##   parameter_type      prior posterior
## 1 Inverse-Gamma on sigma^2 a_0    a_star
## 2 Inverse-Gamma on sigma^2 b_0    b_star
## 3 Multivariate t on beta    mu_0    mu_star
## 4 Multivariate t on beta    V_0     V_star
##
## Model formula:
## growth ~ sp + dbh + dbh * sp + acne * sp + acpl * sp + acru * sp + acsp * sp + aial
```

181 Next, the generic for `predict()` takes as inputs the posterior parameter values in
 182 `comp_bayes_lm_scbi` and the predictor variables in `newdata` and outputs a vector of fit-
 183 ted/predicted values \hat{y} of the DBH for each focal tree computed from the posterior predictive
 184 distribution.

```
focal_vs_comp_scbi <- focal_vs_comp_scbi %>%
  mutate(growth_hat = predict(comp_bayes_lm_scbi, newdata = focal_vs_comp_scbi))
```

```
focal_vs_comp_scbi
## # A tibble: 6,296 x 8
##   focal_ID focal_sp    dbh foldID    geometry growth
##   <dbl> <fct>    <dbl> <fct>    <POINT> <dbl>
## 1         4 nysy    13.6  1      (14.2 428) 0.103
## 2         5 havi     8.8  1      (9.4 436) 0.150
## 3        79 tiam    47.7  1      (40 381) -0.161
```

```
## 4      80 caca      5.15 1      (38.7 422)  0.253
## 5      96 libe      2.3  1      (60 310)  0.262
## # ... with 6,291 more rows, and 2 more variables: comp <list>,
## #      growth_hat <dbl>
```

185 We then compare the observed and fitted/predicted growths to compute the root mean
 186 squared error (RMSE) of our model fit.

```
model_rmse <- focal_vs_comp_scbi %>%
  rmse(truth = growth, estimate = growth_hat) %>%
  pull(.estimate)
model_rmse
## [1] 0.128
```

187 Lastly, the generic for `ggplot2::autoplot()` allows us to plot the posterior distribution
 188 of all parameters in Figure 4 (for compactness we only show posteriors for 3 species).

```
# Plot posteriors for only a subset of species
sp_to_plot <- c("litu", "quru", "cagl")

plot1 <- autoplot(comp_bayes_lm_scbi, type = "intercepts", sp_to_plot = sp_to_plot)
plot2 <- autoplot(comp_bayes_lm_scbi, type = "dbh_slopes", sp_to_plot = sp_to_plot)
plot3 <- autoplot(comp_bayes_lm_scbi, type = "competition", sp_to_plot = sp_to_plot)

# Combine plots using patchwork
(plot1 | plot2) / plot3
```

189 These plots give the posterior distributions of parameters from Equation 1. For many
 190 package users they will be of interest because they give insight into the species-specific
 191 competitive interactions. Setting `type = "intercepts"` gives posterior distributions for
 192 $\beta_{0,j}$ and `type = "dbh_slopes"` for $\beta_{dbh,j}$. These give species specific growth independent of
 193 competition. The values of more interest are plotted with `type = 'competition'` which

Figure 4: Fit model: Posterior distributions of all parameters for three species.

gives the posterior distribution for $\lambda_{j,k}$ species-specific competition coefficients (i.e., the λ -matrix). Negative values indicate a competitor species which slows the growth of a focal species. Here, for example, we see that tulip trees (`litu`) have a strong negative effect on the growth of conspecifics but relatively little effect on neighbors of the other two species.

2.5 Evaluate the effect of competitor species identity using permutation tests

In order to evaluate the effect of competitor species identity, we use the four steps of our analysis sequence answer along with a permutation test: Under a null hypothesis where competitor species identity does not matter, we can permute/shuffle this variable within each focal tree, compute the RMSE (the test statistic of interest), repeat this process several times to construct a null distribution of the RMSE, and compare it to the observed RMSE to assess significance. Going back to our example in Section 2.3 of focal tree with `focal_ID` 4 and its 20 competitors, the permutation test randomly resamples the `comp_sp` variable with replacement, leaving all other variables intact. The resampling with replacement is nested within each focal tree in order to preserve the neighborhood structure of our competition

209 model. To run the permutation test, we use the same `comp_bayes_lm()` function as in
210 Section 2.4, but with a `run_shuffle = TRUE` argument.

```
comp_bayes_lm_scbi_shuffle <- focal_vs_comp_scbi %>%  
  comp_bayes_lm(prior_param = NULL, run_shuffle = TRUE)  
  
focal_vs_comp_scbi <- focal_vs_comp_scbi %>%  
  mutate(growth_hat_shuffle = predict(comp_bayes_lm_scbi_shuffle, newdata = focal_vs_comp.  
  
model_rmse_shuffle <- focal_vs_comp_scbi %>%  
  rmse(truth = growth, estimate = growth_hat_shuffle) %>%  
  pull(.estimate)  
model_rmse_shuffle  
## [1] 0.131
```

211 The resulting RMSE of 0.131 based on the permutation test is larger than the earlier
212 RMSE of 0.128, suggesting that models that do incorporate competitor species identity
213 better fit the data. We conduct an analysis of the full SCBI plot in Section below.

214 2.6 Evaluate model performance using spatial cross-validation

215 We answer the second of our two questions: how can we obtain an accurate estimate of
216 model performance/error? The model fits and predictions in Section 2.4 all suffer from a
217 common failing: they use the same data to both fit the model and to assess the model's
218 performance using the RMSE. As argued by Roberts et al. (2017), this can lead to overly
219 optimistic assessments of model quality as the models can be overfit, in particular in situ-
220 ations where spatial-autocorrelation is present. To mitigate the effects of such overfitting,
221 we use a spatially block cross-validation algorithm.

222 To this end, we use the `foldID` variable defined in Section 2.2 whereby all focal trees
223 are assigned to one of 4 spatially contiguous blocks that act as folds in our cross-validation
224 routine. Figure 5 presents a schematic illustrating this scheme for fold 1 (bottom-left)
225 as the test set and folds 2, 3, and 4 as the training sets. We fit the model to all focal

Figure 5: Schematic of spatial cross-validation: Using the $k = 1$ fold as the test set, assigning each focal tree to training set, test set, and fold buffer.

trees in the training set, apply the model to all focal trees in the test set to compute fitted/predicted values, and compute the RMSE of the observed versus predicted growths. We repeat this procedure 3 more times with each of the three remaining folds acting as the test set and then average all four resulting RMSE's. Furthermore, in order to maintain spatial independence between the test and training set, a fold buffer that extend outwards from the boundary of the test set is computed; all trees falling within this fold buffer are excluded from the training set.

This algorithm is implemented in the `run_cv()` function, which is a wrapper function to the `comp_bayes_lm()` function that fits the model and the `predict()` generic that returns fitted/predicted values. We compare these values to the observed growth values to again compute our RMSE.

```
focal_vs_comp_scbi <- focal_vs_comp_scbi %>%
  run_cv(comp_dist = comp_dist, cv_grid = blocks_scbi)
```

```

model_rmse_cv <- focal_vs_comp_scbi %>%
  rmse(truth = growth, estimate = growth_hat) %>%
  pull(.estimate)
model_rmse_cv
## [1] 0.14

```

The resulting RMSE of 0.14 computed using cross-validation is larger than the earlier RMSE of 0.128, suggesting that models that do not take the inherent spatial autocorrelation of the data into account generate error estimates that are overly optimistic; in our case RMSE's that are too low.

3 Discussion

- Run full simulation on SCBI data
- run time considerations

4 Acknowledgments

Sophie Li for her feedback on package interface.
