#### Abstract

- 1. Many models for the growth of trees that incorporate the effect of interspecies competition are based on a neighborhood effect assumption whereby all trees within a fixed distance of all focal trees are considered competitors. Methods and tools are needed to quantify this competitive effect and assess the quality of all resulting models
- 2. We present the forestecology package providing methods for both 1) evaluating the effect of competitor species identity using permutation tests and 2) evaluating model performance using spatial cross-validation. Following Allen & Kim (2020), we implement a Bayesian linear regression competition model.
- 3. We demonstrate the package's functionality using data from the Smithsonian Conservation Biology Institute's large forest dynamics plot, part of the ForestGEO global network of reseach sites. Given ForestGEO's data collection protocols and data formatting standards, the package was designed with cross-site compatibility in mind. We demonstrate that both 1) competitor species identity matters and 2) that not spatially cross-validating leads to error estimates that are overly optimistic.
- 4. The package features 1) tidyverse-like structure whereby verb-named functions can be modularly "piped" in sequence, 2) functions with standardized inputs/outputs of simple features sf package class, and 3) R S3 object-oriented implementation of the Bayesian linear regression model. These three facts allow for clear articulation of all the steps in the sequence of analysis and easy wrangling and visualization of

the geospatial forestry data. Furthermore, while the package only has Bayesian linear regression implemented, the package was designed with extensibility to other methods in mind.

Keywords: forest ecology, competition, R, Rstats, tidyverse, sf, cross-validation, spatial statistics

# 1 Introduction

Repeat-censused forest plots offer excellent data to test neighborhood models of tree competition Allen & Kim (2020) Canham et al. (2006) Uriarte et al. (2004). Here we describe an R package, forestecology, to do that. This package implements the methods in Allen & Kim (2020). It provides: a convenient way to specify and fit models of tree growth based on neighborhood competition; a spatial cross validation method to test and compare model fits Roberts et al. (2017); and an ANOVA-like method to assess whether the competitor identity matters in these models. The model is written to work with ForestGEO plot data Anderson-Teixeira et al. (2015), but we envision that it could easily be modified to work with data from other forest plots, e.g. the US Forest Service Forest Inventory and Analysis plots Smith (2002). 11 The forestecology is designed with "tidy" data principles in mind as Wickham et al. 12 (2019).13 Given that our data is of geo-spatial nature, we represent our data using the "simple 14 features" sf package class of objects Pebesma (2018) whereby. While previously the sp package serves such purposes Pebesma & Bivand (2005), the sf package is designed to interface with the tidyverse suite of packages.

# 8 1.1 Model for growth of tree

26

While there are a litany of models one can consider, in Allen & Kim (2020) we considered a simple one.

We fit the following linear model to the DBH of each focal tree. Let  $i = 1, ..., n_j$  index all  $n_j$  trees of "focal" species group j; let j = 1, ..., J index all J focal species groups; and let k = 1, ..., K index all K "competitor" species groups. We modeled the growth in diameter per year  $y_{ij}$  (in centimeters per year) of the  $i^{th}$  tree of focal species group j as a linear model f of the following covariates  $\vec{x}_{ij}$ 

$$y_{ij} = f(\vec{x}_{ij}) + \epsilon_{ij} = \beta_{0,j} + \beta_{\text{DBH},j} \cdot \text{DBH}_{ij} + \sum_{k=1}^{K} \lambda_{jk} \cdot \text{BA}_{ijk} + \epsilon_{ij}$$

Link to https://doi.org/10.1371/journal.pone.0229930.s004

For this linear model's case, there exists a closed form solution as described here. As such, the fit\_bayesian\_model() function using matrix algebra to obtain all parameter estimates, rather than computationally expensive Monte Carlo approximations. The inputs to this function are a focal\_vs\_comp data frame, prior\_param a list of priors, and a boolean flag run\_shuffle on whether or not to run competitor-species identity permutations which we will demonstrate below on the Michigan Big Woods data. This function returns the posterior means of all parameters.

# 2 Example

- We demonstrate the forestecology package's functionality on data from the Smithsonian Conservation Biology Institute (SCBI) large forest dynamics plot, located at the Smith-36 sonian's National Zoo and Conservation Biology Institute in Front Royal, VA, USA. The 37 25.6 ha (640 x 400 m) plot is located at the intersection of three of the major physiographic provinces of the eastern US: the Blue Ridge, Ridge and Valley, and Piedmont provinces and is adjacent to the northern end of Shenandoah National Park. The forest type is typical mature secondary eastern mixed deciduous forest, with a canopy dominated by tulip poplar (Liriodendron tulipifera), oaks (Quercus spp.), and hickories (Carya spp.), 42 and an understory composed mainly of spicebush (Lindera benzoin), paw-paw (Asimina 43 triloba), American hornbeam (Carpinus caroliniana), and witch hazel (Hamamelis virginiana) Bourg et al. (2013). 45
- The forestecology package has the following ecological goals: 1) to evaluate the effect of competitor species identity using permutation tests and 2) to evaluate model performance using spatial cross-validation. To achieve these goals, we outline a basic analysis sequence comprising of these four main steps:
- 1. Compute the growth of trees based on census data.
- 51 2. Add spatial information:

52

53

- 1. Define a buffer region of trees.
- 2. Add spatial cross-validation block information.
- 3. Identify all focal trees and their competitors.

- 4. Apply model, which includes:
- 1. Fit model.

55

- 57 2. Compute fitted/predicted values.
- <sup>58</sup> 3. Visualize posterior distributions.
- We start by loading all necessary packages.

```
library(tidyverse)
library(lubridate)
library(sf)
library(patchwork)
library(forestecology)
library(blockCV)
```

## 60 2.1 Step 1: Compute the growth of trees based on census data

The first step in the our analysis sequence is to compute the growth of trees using data from two censuses. The compute\_growth() function computes growth assuming census data that roughly follows ForestGEO standards. Despite such standards, minor variations will still exist between sites, thereby necessitating some data wrangling and checking. For example, the SCBI site records all DBH's in millimeters Bourg et al. (2013), whereas the Michigan Big Woods site records them in centimeters Allen et al. (2020).

We load both 2008 and 2014 SCBI census data .csv files as they existed on GitHub on November 20, 2020. After selecting only the relevant variables, we perform a few additional data wrangling steps: convert the character variable with the date of measurement to be of explicit type date, convert DBH to be in centimeters<sup>1</sup>, convert the sp variable containing species information from type chr character to fct factor. Furthermore, in order to speed

<sup>&</sup>lt;sup>1</sup>A rule of thumb to determine the units of DBH is to check if the smallest non-zero and non-missing measurement is 1 or 10. If the former, then centimeters. If the later, then millimeters. This is because ForestGEO protocols state that only trees with DBH greater or equal to 1cm should be included in censuses.

<sup>&</sup>lt;sup>2</sup>In our spatial cross-validation algorithm in Section 2.6 issues can occur when rare species do not occur in the training set, but then are encountered in the test set. This risk is mitigated by representing sp as a factor variable, which has a complete list of all levels of the categorical variable.

up computation for purposes of this example, we only consider a 9 ha subsection of the 25.6 ha of the SCBI site: gx from 0-300 instead of 0-400 and gy from 300-600 instead of 0-640.

```
census_2013_scbi <- read_csv("scbi.stem2.csv") %>%
 select(stemID, sp, date = ExactDate, gx, gy, dbh, codes, status) %>%
 mutate(
   date = mdy(date),
   dbh = as.numeric(dbh)/10,
   sp = factor(sp)
 ) %>%
 filter(gx < 300, between(gy, 300, 600))
census_2018_scbi <- read_csv("scbi.stem3.csv") %>%
 select(stemID, sp, date = ExactDate, gx, gy, dbh, codes, status) %>%
 mutate(
   date = mdy(date),
   dbh = as.numeric(dbh)/10,
   sp = factor(sp)
 ) %>%
 filter(gx < 300, between(gy, 300, 600))
```

These two data frames are then used as arguments to the compute\_growth() function, along with the id argument that specifies the variable that uniquely identifies each treestem. Note furthermore that we discard all resprouts in the later census (those with code
== R).

```
growth_scbi <-
compute_growth(
  census_1 = census_2013_scbi,
  census_2 = census_2018_scbi %>% filter(!str_detect(codes, "R")),
  id = "stemID"
```

```
)
growth_scbi

The output growth\_scbi is a single data frame of class sf that includes growth, the average annual growth in DBH (in cm) for all trees that were alive at both time points, as well a geometry variable encoding each tree's geolocation. Furthermore, the variables that should remain unchanged between censuses appear only once, such as location variables gx and gy; as well as species-related variables. Variables that should change between censuses are suffixed with 1 and 2 indicating the earlier and later censuses, such as dbh1/dbh2 and codes1/codes2.

The data format of other sites may be such that our compute\_growth() function doesn't work at all. However, in the end all that matters is that the growth of all trees is saved in

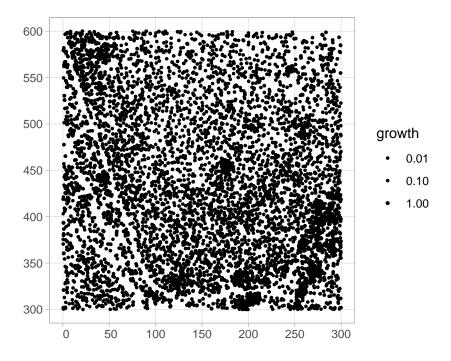

Figure 1: Compute growth of trees based on census data: Map with growth of all trees from a 9 ha subsection of the Smithsonian Conservation Biology Institute (SCBI) forest plot.

- a data frame of class sf whereby the geolocation of each tree is presented in a geometry variable of type <POINT> and at a minimum the data contains the variables above.
- Given that growth\_scbi is of class sf, it can be easily plotted in ggplot2 using the geom\_sf() geometry as seen in Figure 1.

```
# TODO: Rescale points in this plot
ggplot() +
geom_sf(data = growth_scbi, aes(size = growth)) +
scale_size(breaks = c(0.01, 0.1, 1), range = c(0.1, 1))
```

# 92 2.2 Step 2: Add spatial information

- The next step in our analysis sequence is to add spatial information to our main growth\_scbi
- data frame. The first element of spatial information we add is a "buffer region" to the pe-
- <sup>95</sup> riphery of the study region. Since some of our model's explanatory variables are cumulative

(such as competitor basal area), we must ensure that all trees being modeled are not biased to have different neighbor structures. This is of concern for trees at the boundary of study regions, which will not have the same number of neighbors as trees in the internal part of the study region. In order to account for such edge effects, only trees that are not part of this buffer region, i.e. are part of the interior of the study region, will have their growths modeled Waller & Gotway (2004).

Our model of interspecific competition relies on a spatial definition of who the com-102 petitor trees are for focal trees of interest: all trees within a distance comp\_dist of a focal 103 tree are considered its competitors (assuming the same units as the gx and gy location 104 variables). In our case we set this value at 7.5m, a value informed by Canham et al. 105 (2004) Uriarte et al. (2004) Canham et al. (2006). Using this value along with a man-106 ually constructed sf object representation of the study region's boundary, we apply the 107 add\_buffer\_variable() to our growth\_scbi data frame to add a buffer boolean variable: 108 all trees who have buffer set to FALSE will be our focal trees whose growths are modeled, 109 whereas those with TRUE will only be considered as competitor trees whose growth will not 110 be modeled.

```
# Define buffer region using competitive distance range
comp_dist <- 7.5

study_region_scbi <- tibble(
    x = c(0, 300, 300, 0, 0),
    y = c(300, 300, 600, 600, 300)
) %>%
    sf_polygon()

growth_scbi <- growth_scbi %>%
    add_buffer_variable(size = comp_dist, region = study_region_scbi)
```

The second element of spatial information are blocks corresponding to folds of a spatial cross-validation algorithm used to estimate out-of-sample model error. Conventional cross-validation algorithms assign observations to folds by randomly resampling individual

112

113

114

observations. However, an assumption that the observations are independent underlies any cross-validation algorithm. In the case of forest census data, observations exhibit spatial autocorrelation. We therefore incorporate this spatial dependence into the cross-validation algorithm by randomly resampling spatial blocks of trees Roberts et al. (2017) Pohjankukka et al. (2017).

In the example below, we first manually define four folds that partition the study region as an sf object. We then use the output of the spatialBlock() function from the

region as an sf object. We then use the output of the spatialBlock() function from the blockCV package to associate each tree in growth\_scbi to the correct fold (saved in the foldID variable) Valavi et al. (2019). <sup>3</sup>

```
# Manually define spatial blocks to act as folds
n_{fold} \leftarrow 4
fold1 <- rbind(c(0, 300), c(150, 300), c(150, 450), c(0, 450))
fold2 <- rbind(c(150, 300), c(300, 300), c(300, 450), c(150, 450))
fold3 <- rbind(c(0, 450), c(150, 450), c(150, 600), c(0, 600))
fold4 \leftarrow rbind(c(150, 450), c(300, 450), c(300, 600), c(150, 600))
blocks_scbi <- bind_rows(</pre>
  sf_polygon(fold1), sf_polygon(fold2), sf_polygon(fold3), sf_polygon(fold4)
) %>%
  mutate(folds = c(1:n_fold) %>% factor())
# Associate each observation to a fold
SpatialBlock_scbi <- spatialBlock(</pre>
  speciesData = growth_scbi, k = n_fold, selection = "systematic",
  blocks = blocks_scbi, showBlocks = FALSE, verbose = FALSE
)
growth_scbi <- growth_scbi %>%
```

<sup>&</sup>lt;sup>3</sup>In the Appendix we present an example where the folds themselves are also created using the spatialBlock() function given a specified cv\_block\_size.

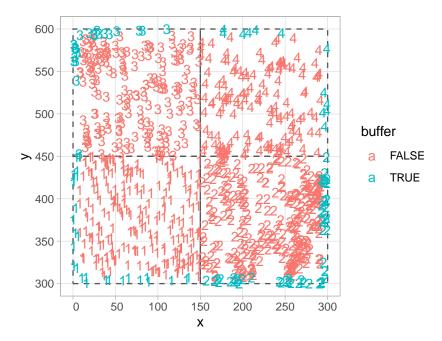

Figure 2: Add spatial information: Buffer region and spatial cross-validation blocks (1 through 4). All trees in the interior of the study region (i.e. not part of buffer) will be the focal trees whose growth will be modeled.

```
mutate(foldID = SpatialBlock_scbi$foldID %>% factor())
```

Figure 2 illustrates the net effect of adding these two elements of information to the growth\_scbi data frame. The location of each tree is marked with an integer indicating which fold it belongs to, where the folds are marked with solid lines. The color of each digit indicates whether the tree is part of the buffer region (and thus will only be considered as a competitor tree in our model) or is part of the interior of the study region (and thus is a focal tree whose growth is of modeled interest).

```
ggplot() +
  geom_sf(data = blocks_scbi, fill = "transparent", linetype = "dashed") +
  geom_sf_text(data = growth_scbi %>% sample_n(1000), aes(label = foldID, col = buffer);
```

### 2.3 Step 3: Identify all focal and corresponding competitor trees

The next step in our analysis sequence is to identify all focal trees and their corresponding 131 competitor trees. The create\_focal\_vs\_comp() functions performs these tasks and returns 132 a new data frame of type sf. On top of the previous arguments comp\_dist defining the 133 competition neighborhood and id indicating which variable uniquely identifies each tree-134 stem, this function also requires an sf object representation of the spatial cross-validation 135 blocks/folds; in our case, this was manually encoded in the blocks\_scbi in Section 2.2 while 136 in our Appendix we present an example where this was performed using spatialBlock() 137 from the blockCV package. We present the resulting data frame below with the foldID variable omitted for compactness of presentation.

```
# TODO: Below reconcile the number of rows as they off by one from growth_scbi %>%
# filter(!is.na(growth) & !buffer). Perhaps by removing NA's in the growth_scbi stage?
focal_vs_comp_scbi <- growth_scbi %>%
  create_focal_vs_comp(comp_dist, cv_grid_sf = blocks_scbi, id = "stemID")
focal_vs_comp_scbi %>%
  select(-foldID)

#### ## # ... with 6,286 more rows

The resulting data frame focal\_vs\_comp\_scbi has 6296 rows, representing the subset of the 7954 trees in growth\_scbi that will be considered as focal trees. Two new variables focal\_ID and focal\_sp relate to tree-stem identification and species information. Most notably however is a new variable comp which contains information on all competitor trees for a given focal tree, saved in tidyr package list-column format Wickham (2020). For example, we drill-down on the tree with focal\_ID 4, which has 20 competitor trees each described by 4 variables as indicated by the fact that comp is a <tibble [20 × 4]>.

The spatial distribution of these trees is visualized in Figure 3: the dashed circle extends
7.5 m away from the focal tree while all 20 competitor trees are within this circle.

Using the unnest() function from the tidyr package, we can flatten list-column into regular columns. We observe that for the same focal tree, we have information on all 20 competitor trees whose dist distance to the focal tree is  $\leq 7.5$ : their unique tree-stem ID number, their species, and their basal area (in m<sup>2</sup>) calculated as  $\frac{\pi \times (DBH/2)^2}{10000}$  where DBH is the value from the earlier of the two censuses in cm. Saving our focal versus competitor information in list-column minimizes redundancy since we do not repeat information on the focal tree 20 times.

```
focal_vs_comp_scbi %>%
  filter(focal_ID == 4) %>%
  select(focal_ID, dbh, comp) %>%
  unnest(cols = "comp")
```

# 165 **2.4** Step 4: Fit model

Now that we've identified all focal and corresponding competitor trees and saved this information in a data frame of type focal\_vs\_comp, the final step in our analysis sequence is to fit a model for the growth of all focal trees. Currently the forestecology package can only fit the competition Bayesian linear regression model outlined in Section 1.1 using the comp\_bayes\_lm() function. However, any model implemented in a function that similarly takes an input data frame of type focal\_vs\_comp as an argument can be easily swapped

in. For our specific competition Bayesian linear regression model, we also specify prior distributions on all parameters of interest (here chosen to be the defaults as specified in ?comp\_bayes\_lm).

```
# TODO: Add information about default priors in ?comp_bayes_lm()
comp_bayes_lm_scbi <- focal_vs_comp_scbi %>%
comp_bayes_lm(prior_param = NULL)
```

The returned comp\_bayes\_lm\_scbi output is an object of S3 class type comp\_bayes\_lm which contains the posterior values of all parameters in our competition Bayesian linear regression. This class of object includes generic methods implemented for print(), predict(), and ggplot2::autoplot(). First the generic for print() displays the names of all prior & posterior parameters along with the model formula:

```
comp_bayes_lm_scbi
## Bayesian linear regression model parameters with a multivariate Normal likelihood.
##
     parameter_type
##
                               prior posterior
## 1 Inverse-Gamma on sigma^2 a_0
                                     a\_star
## 2 Inverse-Gamma on sigma^2 b_0
                                     b\_star
## 3 Multivariate t on beta
                                     mu\_star
                               mu_0
## 4 Multivariate t on beta
                               V_{-}O
                                      V_star
##
## Model formula:
## growth \sim sp + dbh + dbh * sp + acne * sp + acpl * sp + acru * sp + acsp
```

Next, the generic for predict() takes as inputs the posterior parameter values in comp\_bayes\_lm\_scbi and the predictor variables in newdata and outputs a vector of fit-ted/predicted values  $\hat{y}$  of the DBH for each focal tree computed from the posterior predictive distribution.

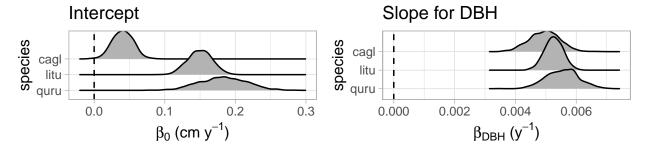

```
focal_vs_comp_scbi <- focal_vs_comp_scbi %>%
  mutate(growth_hat = predict(comp_bayes_lm_scbi, newdata = focal_vs_comp_scbi))
```

```

## 10
## # ... with 6,286 more rows, and 2 more variables: comp <list>,
       growth_hat <dbl>
```

We then compare the observed and fitted/predicted growths to compute the root mean squared error (RMSE) of our model fit.

```
model_rmse <- focal_vs_comp_scbi %>%
    rmse(truth = growth, estimate = growth_hat) %>%
    pull(.estimate)
model_rmse
## [1] 0.1281398
```

Lastly, the generic for ggplot2::autoplot() allows us to plot the posterior distribution of all parameters in Figure 4 (for compactness we only show posteriors for 3 species).

# Competitor species in rows, focal species in columns

Ex: Top row, second column: competitive effect of cagl on litu

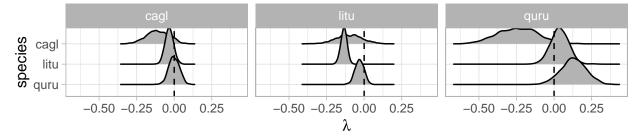

Figure 4: Fit model: Posterior distributions of all parameters for three species.

```
# Plot posteriors for only a subset of species
sp_to_plot <- c("litu", "quru", "cagl")

plot1 <- autoplot(comp_bayes_lm_scbi, type = "intercepts", sp_to_plot = sp_to_plot)
plot2 <- autoplot(comp_bayes_lm_scbi, type = "dbh_slopes", sp_to_plot = sp_to_plot)
plot3 <- autoplot(comp_bayes_lm_scbi, type = "competition", sp_to_plot = sp_to_plot)

# Combine plots using patchwork
(plot1 | plot2) / plot3</pre>
```

TODO: Discuss meaning of results.

188

# 2.5 Evaluate the effect of competitor species identity using permutation tests

In order to evaluate the effect of competitor species identity, we use the four steps of our analysis sequence answer along with a permutation test: Under a null hypothesis where

competitor species identity does not matter, we can permute/shuffle this variable within 193 each focal tree, compute the RMSE (the test statistic of interest), repeat this process several 194 times to construct a null distribution of the RMSE, and compare it to the observed RMSE 195 to assess significance. Going back to our example in Section 2.3 of focal tree with focal\_ID 4 196 and its 20 competitors, the permutation test randomly resamples the comp\_sp variable with 197 replacement, leaving all other variables intact. The resampling with replacement is nested 198 within each focal tree in order to preserve the neighborhood structure of our competition 199 model. To run the permutation test, we use the samecomp\_bayes\_lm() function as in 200 Section 2.4, but with a run\_shuffle = TRUE argument. 201

```
comp_bayes_lm_scbi_shuffle <- focal_vs_comp_scbi %>%
  comp_bayes_lm(prior_param = NULL, run_shuffle = TRUE)

focal_vs_comp_scbi <- focal_vs_comp_scbi %>%
  mutate(growth_hat_shuffle = predict(comp_bayes_lm_scbi_shuffle, newdata = focal_vs_comp_scbi %>%
  model_rmse_shuffle <- focal_vs_comp_scbi %>%
  rmse(truth = growth, estimate = growth_hat_shuffle) %>%
  pull(.estimate)

model_rmse_shuffle
## [1] 0.131083
```

The resulting RMSE of 0.131083 based on the permutation test is larger than the earlier RMSE of 0.1281398, suggesting that models that do incorporate competitor species identity better fit the data. We conduct a fuller simulation in Section below.

# 2.6 Evaluate model performance using spatial cross-validation

We answer the second of our two questions: how can we obtain an accurate estimate of model performance/error? The model fits and predictions in Section 2.4 all suffer from a common failing: they use the same data to both fit the model and to assess the model's performance using the RMSE. As argued by Roberts et al. (2017), this can lead to overly

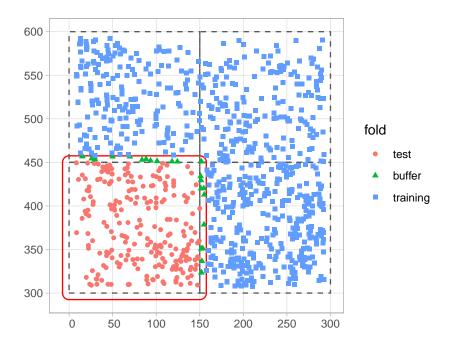

Figure 5: Schematic of spatial cross-validation: Using the k = 1 fold as the test set, assigning each focal tree to training set, test set, and buffer.

optimistic assessments of model quality as the models can be overfit, in particular in situ-210 ations where spatial-autocorrelation is present. To mitigate the effects of such overfitting, we use a spatially block cross-validation algorithm. 212

To this end, we use the foldID variable defined in Section 2.2 whereby all focal trees are assigned to one of 4 spatially contiguous blocks that act as folds in our cross-validation routine. Figure 5 presents a schematic illustrating this scheme for fold 1 (bottom-left) as the test set and folds 2, 3, and 4 as the training sets. We fit the model to all focal trees in the training set, apply the model to all focal trees in the test set to compute fitted/predicted values, and compute the RMSE of the observed versus predicted growths. We repeat this procedure 3 more times with each of the three remaining folds acting as the test set and then average all four resulting RMSE's. Furthermore, in order to maintain spatial independence between the test and training set, a buffer that extend outwards from the boundary of the test set is computed; all trees falling within this buffer are excluded from the training set.

This algorithm is implemented in the run\_cv() function, which is a wrapper function to the comp\_bayes\_lm() function that fits the model and the predict() generic that returns fitted/predicted values. We compare these values to the observed growth values to again compute our RMSE.

```
focal_vs_comp_scbi <- focal_vs_comp_scbi %>%
  run_cv(comp_dist = comp_dist, cv_grid = blocks_scbi)
```

```
model_rmse_cv <- focal_vs_comp_scbi %>%
  rmse(truth = growth, estimate = growth_hat) %>%
 pull(.estimate)
model_rmse_cv
## [1] 0.1402209
```

The resulting RMSE of 0.1402209 computed using cross-validation is larger than the 228 earlier RMSE of 0.1281398, suggesting that models that do not take the inherent spatial 229 autocorrelation of the data into account generate error estimates that are overly optimistic; 230 in our case RMSE's that are too low. 231

#### Discussion 3

- Run full simulation on SCBI data 233
- run time considerations 234

# Acknowledgments

Sophie Li for her feedback on package interface.
